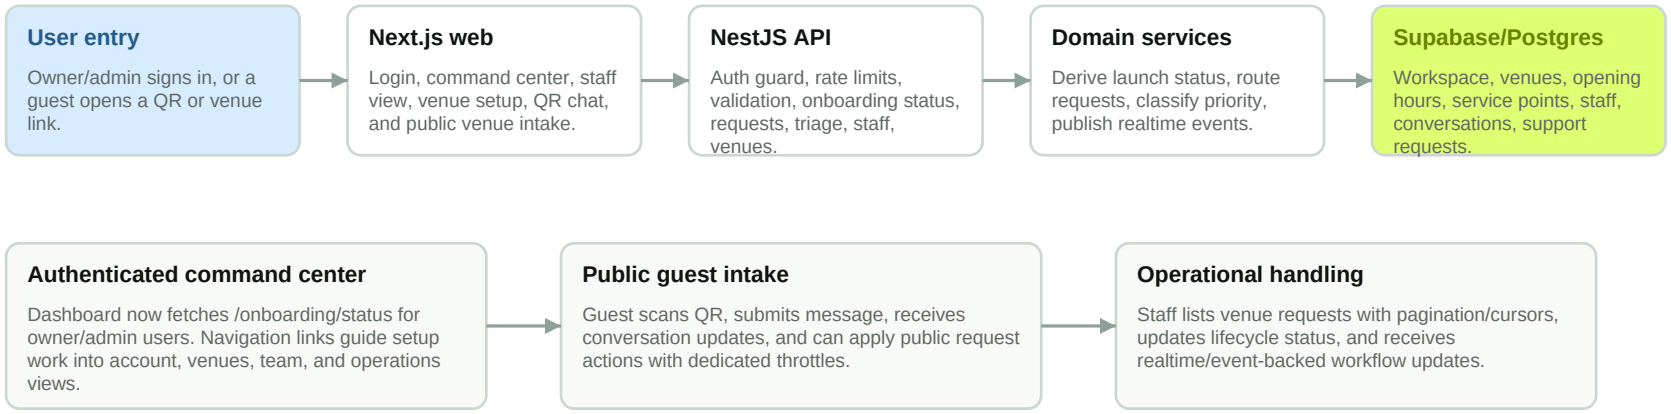
GuestOS Latest Product Flow

Current command center, onboarding, QR intake, API, and database path.



Latest production-readiness additions

1. Owner/admin launch checklist is derived from existing database state, avoiding duplicated onboarding state.

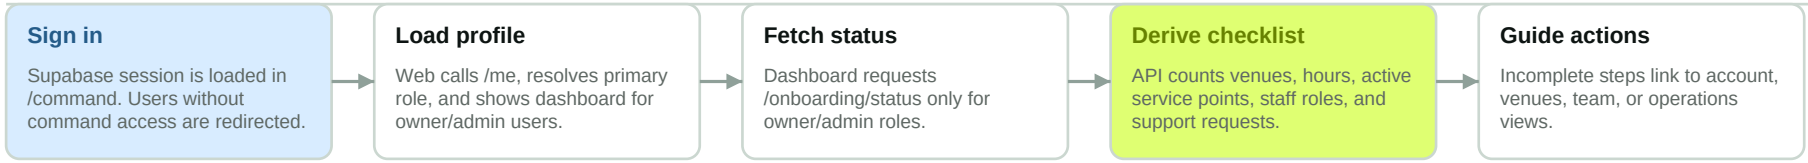
2. Venue request list supports page/cursor/limit and status filters for faster operation across multiple venues.

3. SupportRequest has a venueId + createdAt index migration for common venue timeline queries.

4. API hardening covers production security headers, env validation, nested log redaction, rate limits, and stronger guest-session randomness.

Owner/Admin Onboarding Flow

Launch checklist derived by GET /onboarding/status.



Checklist completion rules

Foundation

Workspace exists, at least one venue exists, and at least one venue has opening hours.

Launch setup

At least one active service point/QR exists and an operational teammate is active.

End-to-end proof

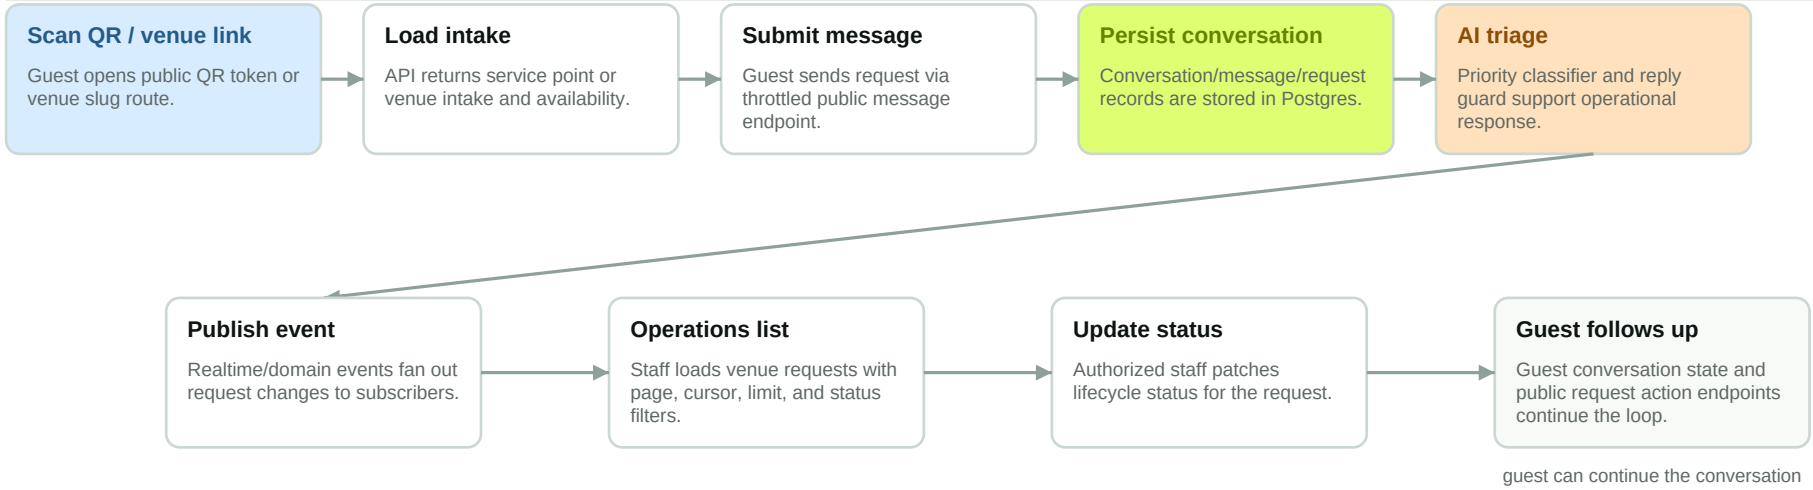
At least one support request has reached the operations workflow.

Why this is production-friendly

The onboarding flow does not depend on a separate mutable checklist table. It reflects actual operational readiness from the source-of-truth tables, remains accurate after edits/imports, and can be recalculated safely for every owner/admin dashboard load.

Guest Request Lifecycle

Public QR intake to operations queue and realtime workflow.



Scale path for 10 venues

The hot operations query is scoped by venue and ordered by createdAt. The latest migration adds an index on SupportRequest venue ID + createdAt, and the list endpoint can return capped pages with nextCursor. That keeps dashboard and operations reads bounded as venue count and request volume grow.

Production Controls Map

Security, performance, and deployment controls around the flow.

Security hardening

1. Supabase auth guard on command APIs.
2. Role checks for owner/admin onboarding status.
3. Global throttling plus stricter public QR throttles.
4. Production security headers and CORS validation.
5. Nested sensitive log redaction.

Data and migrations

1. Prisma schema remains the model source.
2. Supabase SQL migrations are the deployment path.
3. Latest migration adds SupportRequest venue timeline index.
4. Existing production DB should be baselined, not prisma migrate deployed.

Operations efficiency

1. Venue-scoped request listing.
2. Cursor pagination and capped page size.
3. Status/statusGroup filters for active and terminal queues.
4. Dashboard checklist uses small counts only.

Recommended handoff checklist

1. Deploy Supabase migrations with the Supabase CLI after linking the production project.
2. Confirm production env variables meet the stricter API validation rules before deploy.
3. Smoke test owner/admin command center, team invite, venue setup, QR intake, and operations status updates.
4. Monitor request list latency by venue after live traffic begins.
